Each age group offers a different recruitment advantage:

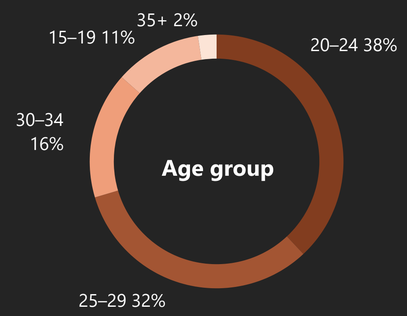

15–19: **Highest average POT (74)**, offering the strongest long-term development potential.

20–24: **Largest player population**, providing the widest range of recruitment options.

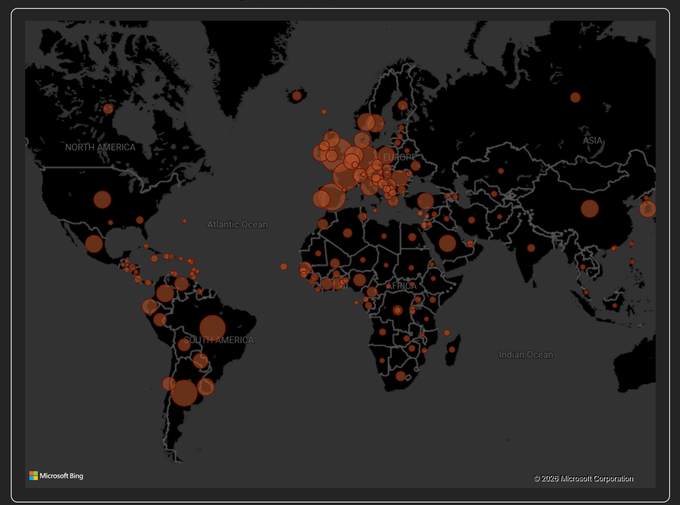

25–29: **Highest average market value**, representing players with strong market demand and investment value.

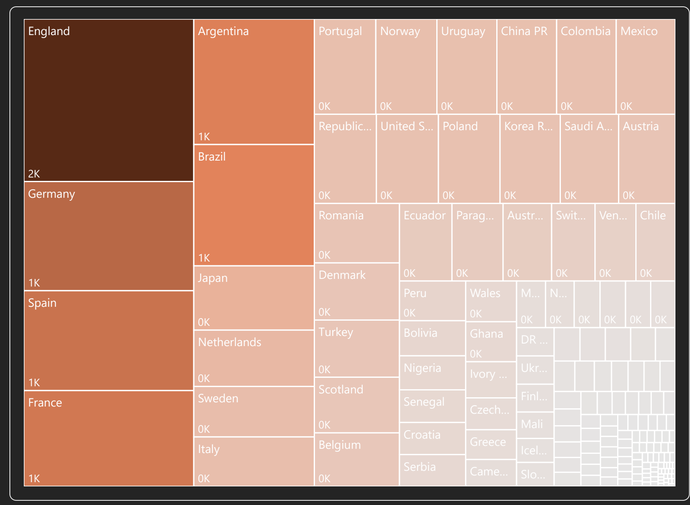

30+: **Highest average OVA**, offering greater current playing ability and potential short-term contribution.

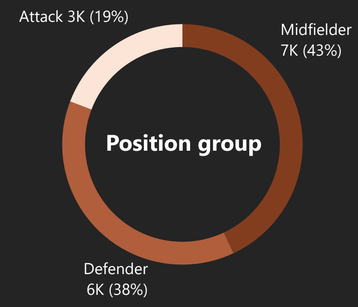

=>**Age** is an important factor in player **development** and **recruitment**. Clubs should invest in young players with high potential for the future while recruiting experienced players to improve current team performance.

Geographical players Distribution

Although **Midfielders** account for the largest player group (43%), followed by **Defenders** (37.8%) and **Attackers** (19.2%), **CB** (Centre Back) and **ST** (Striker) are among the two most populated individual positions.

=>This may reflect the importance of defensive stability and goal-scoring capabilities in football squad structures. Further analysis of Average Wage and Market Value by position can help determine whether the high player population in these positions is associated with higher recruitment costs or greater market value.

Squad Quality by Age Group

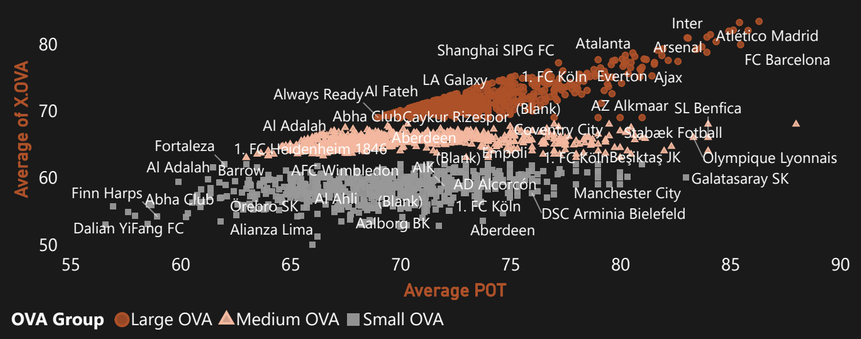

Insight: Age Profile Determines Club Development Strategy

Players aged 15–19 have the highest Average POT, making clubs with a higher proportion of young players more suitable for long-term development.

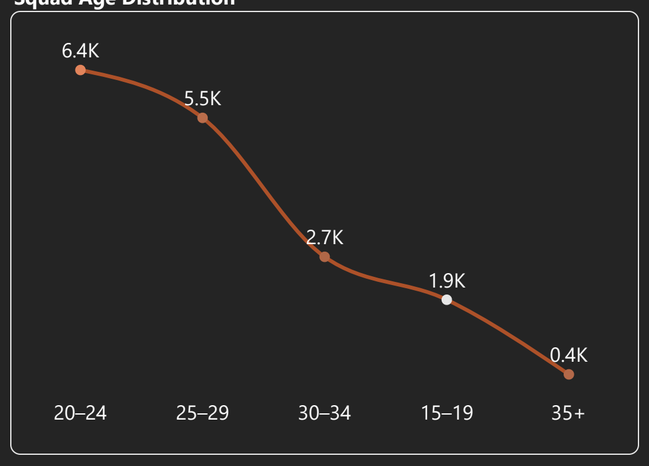

In contrast, players aged 25 and above tend to have higher Average OVA, making clubs with more mature players better suited for immediate competitive performance.

Average POT and Average of X.OVA
by Club and OVA Group

OVA Group Large OVA · Medium OVA · Small OVA

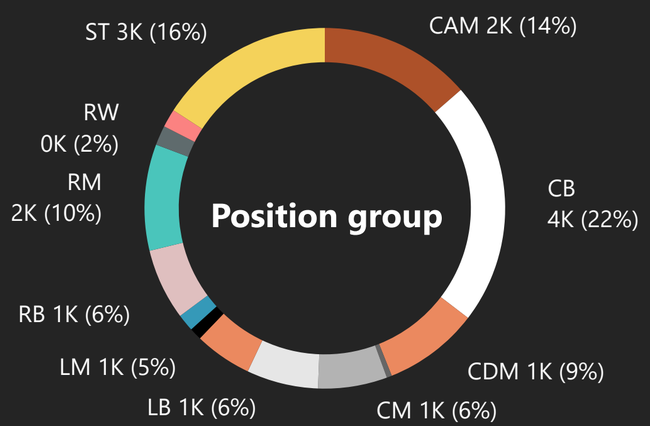

Squad Age Distribution

Average Wage, Sum of Average Value and Count of Value Group
by Club and Wage Group

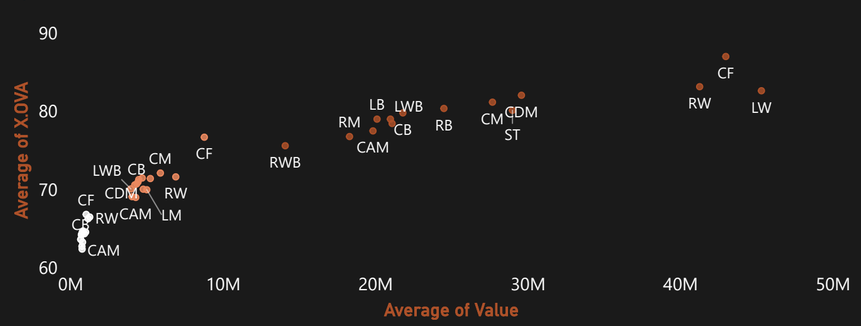

Wage Group High · Low · Medium · Very High · Very Low

CB accounts for the largest share (22%), while RW represents only around 2%, indicating an uneven distribution of players across positions.

Therefore, recruiters should pay closer attention to positions with limited player supply, such as RW, while positions with a larger talent pool, such as CB, offer more options for comparing player quality and recruitment costs.

Average of Value and Average of X.OVA
by BP and POT Group

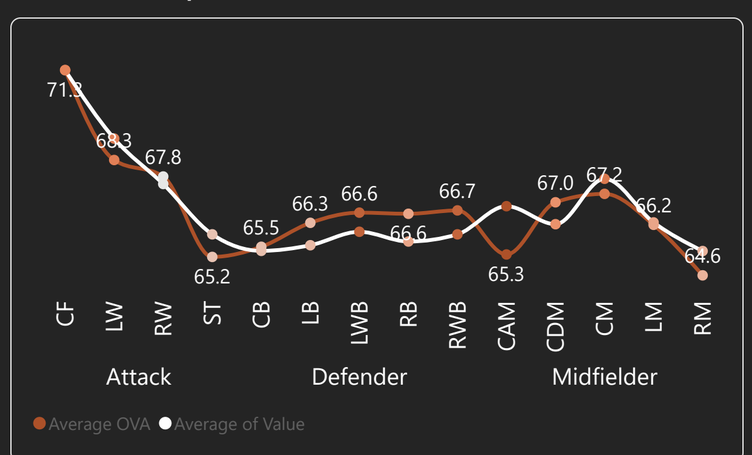

POT Group High Potential · Low Potential · Medium Potential

The chart shows that **CAM** has a relatively **low Average OVA** (approximately **65.3)** compared to many other positions. However, when compared with the Average Value chart, CAM players have higher market values than some positions with better OVA ratings.

This suggests that player market value is not determined solely by current performance (OVA), but may also be influenced by potential (POT), age, and market demand.

By comparing each **club's average OVA**, Wage, and Market Value, we can identify players who best balance performance and financial **requirements**. Since **defenders** have the highest average OVA, their performance level can serve as a benchmark for identifying improvement opportunities in other position groups. This helps clubs build a more balanced squad while maintaining financial efficiency.

Attack	ST	27	D. Thomalla	67	67	825000	9000

Based on the **Show in Starting XI** column, we selected the **player with the highest OVA** at **each position** to evaluate the club's starting lineup. Since the goalkeeper (GK) position is excluded from this analysis, we focus on 10 outfield positions. However, the club currently has only 9 out of 10 required players, with RW being the missing position. We also checked whether any existing players could cover RW as an alternative position, but no suitable option was found. Therefore, the next step is to identify potential RW candidates in the transfer market by evaluating their OVA, POT, Wage, and Market Value against the club's requirements.

Key Insight: The club has a **shortage of right-wingers (RW),** making this position a recruitment priority.

Position Category	BP	Age	Name	X.OVA	POT	Value	Wage
Defender	CB	25	P. Mainka	73	75	4300000	17000
Defender	RB	25	M. Busch	71	75	2700000	14000
Defender	CB	27	O. Hüsing	70	72	1900000	12000
Defender	LB	33	N. Theuerkauf	72	72	1400000	16000

Position Category	BP	Age	Name	X.OVA	POT	Value	Wage
Midfielder	CM	28	K. Kerschbaumer	70	70	1800000	14000
Midfielder	CDM	28	A. Geipl	68	68	800000	9000
Midfielder	CAM	19	K. Sessa	61	76	525000	2000

To improve squad balance, the club should aim to maintain a consistent OVA level across all starting positions. Therefore, the highest OVA score among current players will be used as a benchmark to identify performance gaps and determine which positions need improvement. This helps establish a more balanced and competitive starting XI.

CB	25	P. Mainka	73	75	49	75	77	76	77	72	73	83	50
CB	27	O. Hüsing	70	72	46	70	79	63	71	67	76	90	55

This analysis focuses on developing player **O. Hüsing using P. Mainka as a benchmark.**

I used R to build a Multiple Linear Regression model based on the entire FIFA dataset of CB players to **identify the relationships between player attributes and OVA.** The model achieved an Adjusted R-squared of 96.32%.

The results identified three key skills that Hüsing should prioritize improving: Interceptions, Standing Tackle, and Sliding Tackle. **Interceptions** should be the first priority because it has the largest gap compared to the benchmark (+13 points) and the highest regression coefficient. Standing Tackle (+6 points) ranks second, followed by Sliding Tackle (+5 points).

Finally, I developed four hypothetical scenarios to simulate potential changes in OVA. The results show that if Hüsing reaches Mainka's benchmark in all three defensive skills, **his predicted OVA could increase from 69.54 to 75.68**, representing an improvement of 6.14 points. This analysis helps the club establish training priorities and develop a data-driven player development strategy.
